p8106_hw3_yg2625 Yue Gu April 9, 2019

This questions will be answered using the Weekly data set, which is part of the ISLR package. This data is similar in nature to the Smarket data on the textbook except that it contains 1,089 weekly returns for 21 years, from the beginning of 1990 to the end of 2010. A description of the data can be found by typing ?Weekly in the Console. (Note that the column Today is not a predictor.)

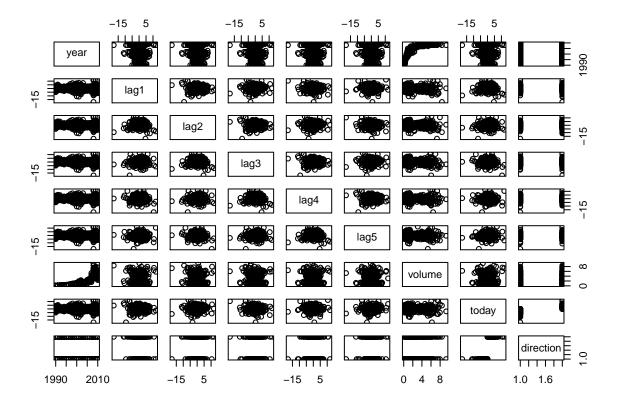

Load Data

```
data("Weekly")
weekly = Weekly %>%
 janitor::clean names()
head(weekly)
                                          volume today direction

```

(a) Produce some graphical summaries of the Weekly data.

pairs scatterplot
pairs(weekly)

(b) Use the full data set to perform a logistic regression with Direction as the response and the five Lag variables plus Volume as predictors. Do any of the predictors appear to be statistically significant? If so, which ones?

```
glm.fit <- glm(direction ~ lag1 + lag2 + lag3 + lag4 + lag5 + volume,</pre>
               data = weekly,
               family = binomial)
summary(glm.fit)
##
## Call:
## glm(formula = direction ~ lag1 + lag2 + lag3 + lag4 + lag5 +
##
       volume, family = binomial, data = weekly)
##
## Deviance Residuals:

## 'Positive' Class : Up
##
```

Based on the output, the confusion matrix provides us with following results:

- 1. Accuracy = 0.5611: provides the probability of the correct classifer, which is the overall fraction of correct predictions. ((TP+TN)/n = (54+557)/1089)
- 2. NIR = 0.5556: provides the larger proportion of total positive observation vs. the proportion of total negative observations. $(\max((TP+FP)/n, (FN+TN)/n))$
- 3. **Kappa = 0.035:** measures the agreement between classification and truth values. A kappa value closed to 1 meaning a good performance of the model.
- 4. **Sensitivity** = 0.9207: measures the proportion of actual positives that are correctly identified. (TP/(TP+FN))
- 5. **Specificity** = **0.1116:** measures the proportion of actual negatives that are correctly identified. (TN/(FP+TN))

(d) Plot the ROC curve using the predicted probability from logistic regression and report the AUC.

```
roc.glm <- roc(weekly$direction, test.pred.prob)
plot(roc.glm, legacy.axes = TRUE, print.auc = TRUE)
plot(smooth(roc.glm), col = 4, add = TRUE)</pre>
```

AUC = 0.554.

(e) Now fit the logistic regression model using a training data period from 1990 to 2008, with Lag1 and Lag2 as the predictors. Plot the ROC curve using the held out data (that is, the data from 2009 and 2010) and report the AUC.
